Do You Feel the AGI Yet?

According to some predictions, 2026 is the year that an all-powerful AI will arrive.

Main Findings

- The article explores whether society is close to achieving artificial general intelligence (AGI) and highlights the **uncertainty and disagreement among leading AI experts**, including **Demis Hassabis**. A central argument is that despite rapid advancements in AI systems, current technologies still fall short of true human-like intelligence.
- Hassabis explains that today's AI can perform impressive tasks but lacks deeper capabilities such as **general reasoning, adaptability across domains, and true understanding**. The article also emphasizes that there is **no consensus on when AGI will arrive**, with predictions ranging from a few years to several decades. This disagreement reflects how complex and unpredictable AI development remains.

Broader Implications for Society

- The article suggests that AI is already shaping society, but its long-term impact is still unclear. One major issue is the **gap between public perception and reality**—many people believe AI is closer to human-level intelligence than it actually is.
- At the same time, the possibility of AGI raises significant concerns, including:
 - How it could transform economies and job markets
 - The need for responsible development and governance
 - The challenge of preparing society for a technology that is not fully understood
- Overall, the article portrays AI as a powerful but still **incomplete technology**, with major societal consequences depending on how it evolves.

Relevance and Potential Influence on the Construction Industry

- The article's insights apply directly to construction and BIM/VDC workflows. While AI has the potential to improve efficiency—such as automating coordination, scheduling, and data analysis—it is **not yet capable of handling complex, real-world decision-making independently**.
- In construction:
- AI can assist with modeling, clash detection, and planning
- Human expertise is still required for judgment, coordination, and problem-solving
- Overreliance on AI could introduce risks due to its current limitations
- ☐ Key takeaway:
AI will likely **enhance productivity in construction**, but it will remain a **support tool rather than a replacement for skilled professionals** in the near future.
